

### Lesson at a Glance

1. Only one tangent is possible at a point on the circle.
2. No tangent is possible from a point in the interior of a circle, to the circle.
3. At most two tangents can be drawn from a point in the exterior of a circle, to the circle.
4. The lengths of the two tangents drawn from an external point to a circle are equal.
5. Tangent at any point on a circle is perpendicular to the radius passing through the point of contact.

## TEXTBOOK QUESTIONS SOLVED

### Exercise 10.1 (Page – 209)

1. How many tangents can a circle have?

**Sol.** A circle can have infinitely many tangents.

2. Fill in the blanks:

- (i) A tangent to a circle intersects it in \_\_\_\_\_ point(s).
- (ii) A line intersecting a circle in two points is called a \_\_\_\_\_.
- (iii) A circle can have \_\_\_\_\_ parallel tangents at the most.
- (iv) The common point of a tangent to a circle and the circle is called \_\_\_\_\_.

**Sol.** (i) one

(ii) secant

(iii) two

(iv) point of contact.

3. A tangent  $PQ$  at a point  $P$  of a circle of radius 5 cm meets a line through the centre  $O$  at a point  $Q$  so that  $OQ = 12$  cm. Length  $PQ$  is:

- (A) 12 cm    (B) 13 cm    (C) 8.5 cm    (D)  $\sqrt{119}$  cm.

**Sol.** (D).

4. Draw a circle and two lines parallel to a given line such that one is a tangent and the other, a secant to the circle.

**Sol.**

Here  $l$  is the given line.  $m$  and  $n$  are respectively, a tangent and a secant to a given circle with centre  $O$  and parallel to line  $l$ .

### Exercise 10.2 (Page – 213-214)

In Q. 1 to 3, choose the correct option and give justification.

1. From a point  $Q$ , the length of the tangent to a circle is 24 cm and the distance of  $Q$  from the centre is 25 cm. The radius of the circle is

- (A) 7 cm    (B) 12 cm    (C) 15 cm    (D) 24.5 cm.

**Sol.**  $r = \sqrt{(25)^2 - (24)^2}$  cm = 7 cm.

Option (A) is correct.

2. In figure, if  $TP$  and  $TQ$  are the two tangents to a circle with centre  $O$  so that  $\angle POQ = 110^\circ$ , then  $\angle PTQ$  is equal to

- (A)  $60^\circ$     (B)  $70^\circ$   
(C)  $80^\circ$     (D)  $90^\circ$ .

**Sol.**  $\because$   $TQ$  and  $TP$  are tangents to a circle with centre  $O$ ,  
such that  $\angle POQ = 110^\circ$

$\therefore OP \perp PT$  and  $OQ \perp QT$

$\Rightarrow \angle OPT = 90^\circ$  and  $\angle OQT = 90^\circ$

Now, in the quadrilateral  $TPOQ$ , we get

$$\therefore \angle PTQ + 90^\circ + 110^\circ + 90^\circ = 360^\circ$$

$$\Rightarrow \angle PTQ + 290^\circ = 360^\circ$$

$$\Rightarrow \angle PTQ = 360^\circ - 290^\circ = 70^\circ$$

Thus, the correct option is (B).

3. If tangents PA and PB from a point P to a circle with centre O are inclined to each other at angle of  $80^\circ$ , then  $\angle POA$  is equal to

(A)  $50^\circ$       (B)  $60^\circ$       (C)  $70^\circ$       (D)  $80^\circ$ .

**Sol.**  $\angle POA = \frac{1}{2} \angle AOB = \frac{1}{2} \times 100^\circ = 50^\circ$ .

Option (A) is correct.

4. Prove that the tangents drawn at the ends of a diameter of a circle are parallel.

**Sol.** In the figure, we have:

PQ is diameter of the given circle and O is its centre.

Let tangents AB and CD be drawn at the end points of the diameter PQ.

Since the tangent at a point to a circle is perpendicular to the radius through the point.

$$\therefore PQ \perp AB \Rightarrow \angle APQ = 90^\circ$$

And  $PQ \perp CD \Rightarrow \angle PQD = 90^\circ$

$$\Rightarrow \angle APQ = \angle PQD$$

But they form a pair of alternate angles.

$$\therefore AB \parallel CD.$$

5. Prove that the perpendicular at the point of contact to the tangent to a circle passes through the centre.

**Sol.** Let perpendicular at the point of contact to the tangent does not pass through at centre.

$$OP \perp PT \quad \dots(i) \text{ [Given]}$$

Join OP. As OP is radius.

$$\therefore O'P \perp PT \quad \dots(ii)$$

[Radius is perpendicular to tangent at the point of contact.]

From (i) and (ii), we get

OP and O'P are perpendicular to PT

$\Rightarrow$  OP and O'P must coincide.

As only one perpendicular can be drawn from a point on a line.

Hence perpendicular from the point of contact, passes through the centre.

6. The length of a tangent from a point A at distance 5 cm from the centre of the circle is 4 cm. Find the radius of the circle.

**Sol.**  $OT = \sqrt{5^2 - 4^2}$   
 $\text{cm} = \sqrt{9} \text{ cm} = 3 \text{ cm}.$

7. Two concentric circles are of radii 5 cm and 3 cm. Find the length of the chord of the larger circle which touches the smaller circle.

**Sol.**  $OA = 5 \text{ cm}, OT = 3 \text{ cm}$

Also  $OT \perp AB,$

Therefore,  $AT = \sqrt{25 - 9} \text{ cm} = 4 \text{ cm}$

$\therefore AB = 2AT = 8 \text{ cm}.$

8. A quadrilateral ABCD is drawn to circumscribe a circle (see figure). Prove that

$$AB + CD = AD + BC$$

**Sol.** We have  $AS = AP$ ;  $BP = BQ$ ;  $CQ = CR$  and  $DR = DS$ .  
 Consider  $AB + CD = (AP + PB) + (CR + RD)$   
 $= AS + BQ + CQ + DS$   
 $= (AS + DS) + (BQ + CQ)$   
 $= AD + BC$ .

**Hence proved.**

**9.** In figure,  $XY$  and  $X'Y'$  are two parallel tangents to a circle with centre  $O$  and another tangent  $AB$  with point of contact  $C$  intersecting  $XY$  at  $A$  and  $X'Y'$  at  $B$ . Prove that  $\angle AOB = 90^\circ$ .

**Sol. Given:** A circle with centre  $O$  has three tangents  $XY$ ,  $X'Y'$  and  $AB$  at the points  $P$ ,  $Q$  and  $C$  respectively. Also  $XY \parallel X'Y'$ .

**To prove:**  $\angle AOB = 90^\circ$

**Construction:** Join  $OC$ ,  $OP$ ,  $OQ$ .

**Proof:** In  $\triangle AOP$  and  $\triangle AOC$ ,

$PA = PC$  [Two tangents drawn from a point outside the circle]

$PO = CO$  [Radii of same circle]

$AO = AO$  [Common]

Therefore,  $\triangle AOP \cong \triangle AOC$  [SSS criterion]

$\therefore \angle 1 = \angle 2$  ...*(i)*

Similarly, we can prove that

$\angle 3 = \angle 4$  ...*(ii)*

Now,  $\angle PAB + \angle QBA = 180^\circ$  [Sum of interior angles on the same side of transversal]

$\Rightarrow 2\angle 2 + 2\angle 3 = 180^\circ$  [Using (i) and (ii)]

$\Rightarrow \angle 2 + \angle 3 = 90^\circ$  [Sum of angles of a triangle is  $180^\circ$ ]

$\Rightarrow \angle AOB = 90^\circ$ . **Hence proved.**

10. Prove that the angle between the two tangents drawn from an external point to a circle is supplementary to the angle subtended by the line-segment joining the points of contact at the centre.

Sol.  $\angle OAP = \angle OBP = 90^\circ$  ... (i)

Also  $\angle AOB + \angle OBP + \angle BPA + \angle OAP = 360^\circ$

[Sum of angles of a quadrilateral is  $360^\circ$ ]

$\Rightarrow \angle AOB + 90^\circ + \angle BPA + 90^\circ = 360^\circ$

$\Rightarrow \angle AOB + \angle BPA = 180^\circ$ .

11. Prove that the parallelogram circumscribing a circle is a rhombus.

Sol.  $AB = CD$  and  $BC = DA$  ... (i)

$AB + CD = AP + BP + CR + DR$   
 $= AS + BQ + CQ + DS$   
 $= AD + BC$

$\Rightarrow 2AB = 2AD$

$\Rightarrow AB = AD$

As adjacent sides of a parallelogram are equal.

$\therefore$  Parallelogram is a rhombus.

[Using (i)]

12. A triangle ABC is drawn to circumscribe a circle of radius 4 cm such that the segments BD and DC into which BC is divided by the point of contact D are of

lengths 8 cm and 6 cm respectively (see figure). Find the sides AB and AC.

**Sol.** Let the circumcircle touches AB and AC at E and F respectively.

Join OA, OB, OC, OE and OF.

We have

$$OD = 4 \text{ cm} = OE = OF \quad [\text{Radii}]$$

Also  $CD = 6 \text{ cm} = CF$ ,  $BD = 8 \text{ cm} = BE$

and  $AE = AF = x \text{ cm}$  [Say]

[ $\because$  The lengths of the two tangents from an external point to a circle are equal]

From figure,

$$ar(\triangle ABC) = ar(\triangle OAB) + ar(\triangle OBC) + ar(\triangle OCA) \dots(i)$$

But  $ar(\triangle ABC) = \sqrt{s(s-a)(s-b)(s-c)}$

$$= \sqrt{(14+x)(14+x-8-x)(14+x-14)(14+x-6-x)}$$

$$\left[ \because s = \frac{AB+BC+CA}{2} = \frac{8+x+8+6+6+x}{2} = 14+x \right]$$

$$= \sqrt{(14+x)6 \times x \times 8} = \sqrt{48x(14+x)}.$$

$$ar(\triangle OAB) = \frac{1}{2} \times (8+x) \times 4 = 16 + 2x$$

$$ar(\triangle OBC) = \frac{1}{2} (6+8) \times 4 = 28$$

and  $ar(\triangle OCA) = \frac{1}{2} (6+x) \times 4 = 12 + 2x$

Now, putting these values in eqn. (i), we have

$$\sqrt{48x(14+x)} = (16+2x) + (28) + (12+2x)$$

$$\Rightarrow \sqrt{48x(14+x)} = 56 + 4x = 4(14+x)$$

$$\Rightarrow 48x(14+x) = 16(14+x)^2 \quad [\text{Squaring both sides}]$$

$$\Rightarrow 48x(14+x) - 16(14+x)^2 = 0$$

$$\Rightarrow 16(14+x)(3x-14-x) = 0$$

$$\Rightarrow 16(14+x)(2x-14) = 0$$

$$\Rightarrow x = -14, 7$$

Ignoring  $x = -14$  because length cannot be negative.

$$\therefore x = 7 \text{ cm}$$

$$\text{Hence, } AB = BE + AE = 8 + x = 8 + 7 = 15 \text{ cm}$$

$$\text{and } AC = CF + AF = 6 + x = 6 + 7 = 13 \text{ cm.}$$

13. Prove that opposite sides of a quadrilateral circumscribing a circle subtend supplementary angles at the centre of the circle.

**Sol.**  $\triangle AOP \cong \triangle AOS$

[As  $AP = AS$ ,  $OP = OS$ ,

$AO$  is common]

$$\angle 1 = \angle 8$$

Similarly  $\angle 2 = \angle 3$

$$\angle 4 = \angle 5$$

$$\angle 6 = \angle 7$$

$$\Rightarrow \angle 1 + \angle 2 + \angle 3 + \angle 4 + \angle 5 + \angle 6 + \angle 7 + \angle 8 = 360^\circ$$

$$\Rightarrow 2\angle 1 + 2\angle 2 + 2\angle 6 + 2\angle 5 = 360^\circ$$

$$\Rightarrow (\angle 1 + \angle 2) + (\angle 6 + \angle 5) = 180^\circ$$

$$\Rightarrow \angle AOB + \angle COD = 180^\circ$$

Similarly, we can show

$$\angle AOD + \angle BOC = 180^\circ$$
